Motivation

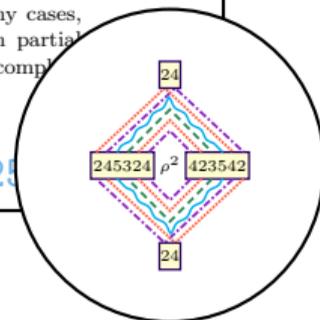

IDEMPOTENTS, TRACES, AND DIMENSIONS IN HECKE CATEGORIES

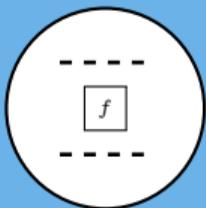

BEN ELIAS, LIAM ROGEL AND DANIEL TUBBENHAUER

ABSTRACT. We explain how to compute idempotents that correspond to the indecomposable objects in the Hecke category. Closed formulas are provided for some common coefficients that appear in these idempotents. We also explain how to compute categorical dimensions in the asymptotic Hecke category. In many cases, we reduce this to a computation of a partial trace and give recursive formulas for some common partial traces. In the sequel, we apply this technology and perform additional (computer) calculations to compute dimensions in the asymptotic Hecke category for finite Coxeter groups in all but three cells.

Diagrammatic Hecke Category

Soergel bimodules

Fix a Coxeter system (W, S) .

Definition (Geometric representation)

- > Let $V = \bigoplus_{s \in S} \mathbb{R}\alpha_s$ be with with bilinear form $(\alpha_s, \alpha_t) = -\cos(\pi/m_{s,t})$.
- > Define the action $s.\lambda := \lambda - 2(\lambda, \alpha_s)\alpha_s$ and the *Demazure operator* $\partial_s(\lambda) := \frac{\lambda - s.\lambda}{\alpha_s}$.
- > Consider $R := \text{Sym}(V)$ as a polynomial ring $R = \mathbb{R}[\alpha_s \mid s \in S]$ with grading $\deg(\alpha_s) = 2$.

Category of Soergel bimodules

1. **Basic bimodules:** For each $s \in S$, define $B_s = R \otimes_{R^s} R(1)$ where R^s are the s -invariant polynomials.
2. **Bott–Samelson bimodules:** For $w = s_1 \cdots s_k$, define $BS(\underline{w}) = B_{s_1} \otimes_R \cdots \otimes_R B_{s_k}$.
3. **Soergel bimodules:** These are direct summands of finite direct sums of grading shifts of Bott–Samelson bimodules.
4. **Category $\mathbb{S}\text{Bim}$:** Objects are Soergel bimodules, morphisms are graded bimodule homomorphisms.

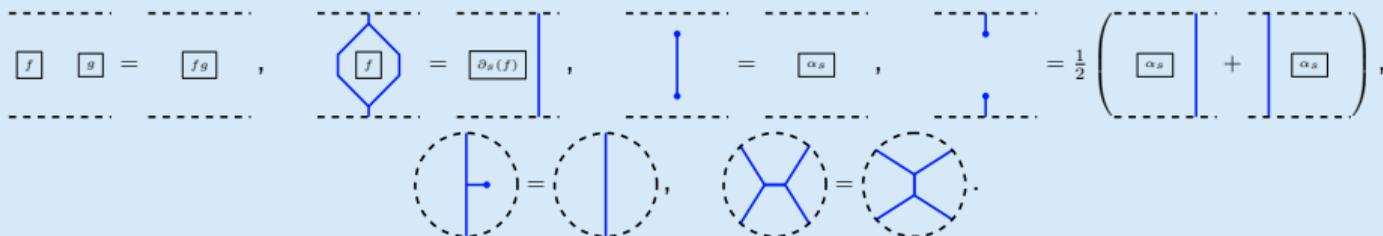

Diagrammatics

Definition (The *diagrammatic Category of Bott–Samelson bimodules* \mathcal{H}_{BS})

- > **Objects:** Sequences of colorful dots on a line. $s \mapsto \bullet$, $t \mapsto \bullet$, \dots
- > **Generating morphisms:** (R, R) -linearly generated by

- > **Relations:** Multiplication, Keyhole, Barbell, Fusion, Frobenius unit/associativity:

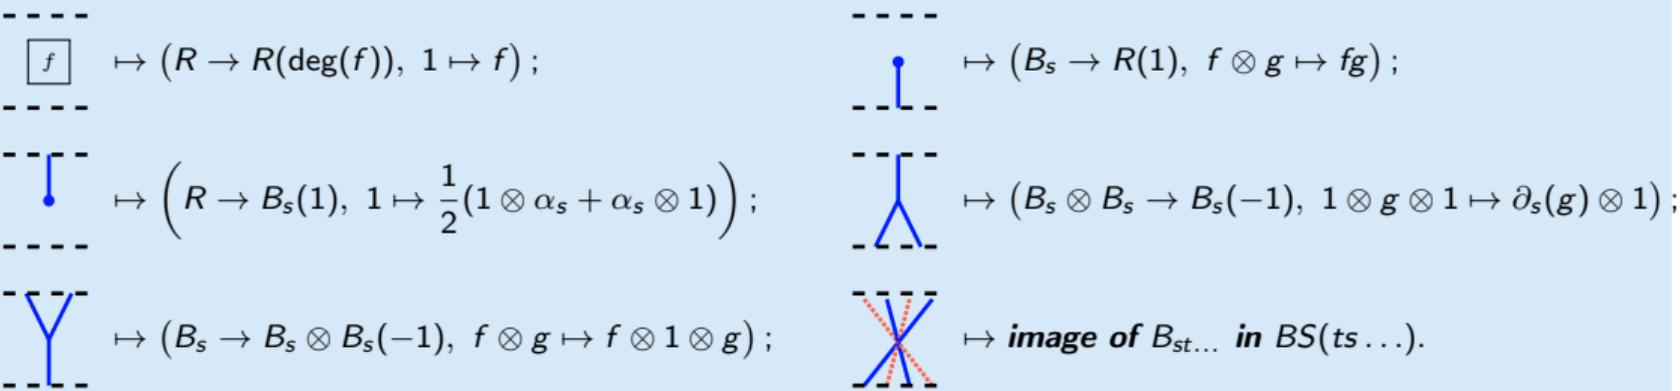

- > And many more 2-color and 3-color relations.

The diagrammatic Hecke category

Theorem (The categories \mathcal{H}_{BS} and $\mathbb{S}\text{Bim}$ are equivalent)

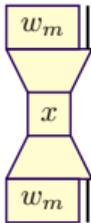

On objects: $\bullet \mapsto B_s$ and multiple dots to tensor products.

On morphisms:

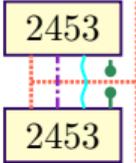

The Karoubian envelope $\mathcal{H} := \text{Kar}(\mathcal{H}_{BS})$ is the idempotent completion of \mathcal{H}_{BS} .

Computing idempotents

$$\sum_{x \in N(w_m) \setminus \{w_{m+1}\}} \kappa_{x, w_{m+1}}^{-1} \cdot$$

The diagram shows a double cone structure. At the top and bottom are yellow boxes labeled w_m . In the center is a white box labeled x . The top and bottom boxes are connected to the central box by yellow trapezoidal shapes that narrow towards the center, forming a double cone.

$$2453 + \frac{1}{[2]_4} \cdot$$

The diagram shows two yellow boxes labeled 2453 stacked vertically. They are connected by a double cone structure. The top and bottom boxes are connected to a central white box labeled x by yellow trapezoidal shapes. The top and bottom boxes are also connected to each other by a double cone structure. The diagram includes colored lines (red, blue, green) and dots (green) indicating connections between the boxes.

Direct sums

Definition

Let X be an object in an additive category. A *direct sum* $X \simeq M \oplus N$ is the data of morphisms

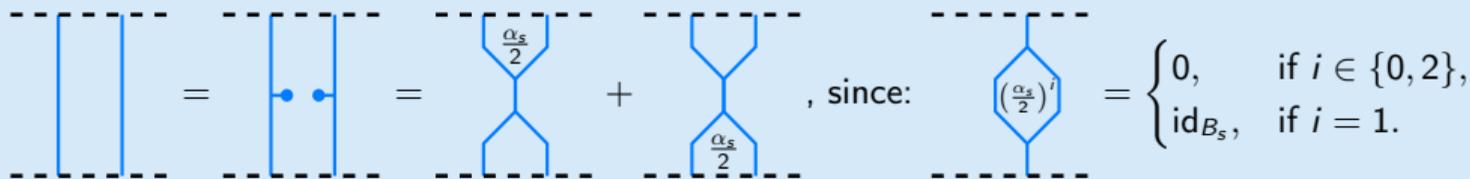

$$\iota_M: M \rightarrow X, \quad \rho_M: X \rightarrow M, \quad \iota_N: N \rightarrow X, \quad \rho_N: X \rightarrow N,$$

which satisfy

$$\text{id}_X = \iota_M \rho_M + \iota_N \rho_N, \quad \rho_M \iota_N = 0, \quad \rho_N \iota_M = 0, \quad \text{id}_N = \rho_N \iota_N, \quad \text{id}_M = \rho_M \iota_M.$$

Example

We have $BS(ss) \simeq B_s(-1) \oplus B_s(+1)$ via:

Dihedral idempotents

Let s, t be reflection with $m_{s,t} > 2$, set $[2] = -\partial_s(\alpha_t) = \partial_t(\alpha_s)$.
 Then $B_s \otimes B_t \otimes B_s \simeq B_{sts} \oplus B_s$ can be seen diagrammatically as

$$\left| \begin{array}{c} | \\ \vdots \\ | \end{array} \right| = \boxed{e} - \frac{1}{[2]} \cdot \begin{array}{c} \diagup \quad \diagdown \\ \vdots \quad \vdots \\ \diagdown \quad \diagup \\ \vdots \quad \vdots \end{array},$$

where \boxed{e} is the orthogonal idempotent projection to B_{sts} since:

$$\begin{array}{c} \diagup \quad \diagdown \\ \vdots \quad \vdots \\ \diagdown \quad \diagup \\ \vdots \quad \vdots \\ \diagup \quad \diagdown \\ \vdots \quad \vdots \\ \diagdown \quad \diagup \\ \vdots \quad \vdots \end{array} \stackrel{\text{Barbell}}{=} \begin{array}{c} \diagup \quad \diagdown \\ \vdots \quad \vdots \\ \alpha_t \\ \vdots \quad \vdots \\ \diagdown \quad \diagup \\ \vdots \quad \vdots \end{array} \stackrel{\text{Keyhole}}{=} -[2] \cdot \begin{array}{c} \diagup \quad \diagdown \\ \vdots \quad \vdots \\ \diagdown \quad \diagup \\ \vdots \quad \vdots \end{array}, \quad \boxed{e} = 0. \quad (1)$$

Clasp idempotents

Definition

We call $X \in \mathcal{H}$ a w -object if it is self-dual and $X \simeq B_w \oplus \bigoplus_{y < w} B_y^{\oplus n_y}$ for $n_y \in \mathbb{N}[v^{\pm 1}]$.

An element $e \in \text{End}^0(X)$ is a *clasp idempotent* if:

1. **Identity coefficient:**

$$\boxed{e} = \text{id}_X + \sum \text{clasp diagram}$$

2. **Annihilation property:** For $\deg(f) + \deg(g) = 0$

$$\text{clasp diagram} = 0.$$

Theorem

If a clasp idempotent $e \in \text{End}^0(X)$ exists, then it is unique and satisfies:

$$\text{Idempotency: } \begin{array}{|c|} \hline e \\ \hline e \\ \hline \end{array} = \boxed{e}, \quad \text{Pre-annihilation: } \begin{array}{|c|} \hline e \\ \hline f \\ \hline g \\ \hline \end{array} = 0, \quad \text{flip-invariance: } \boxed{e} = \boxed{\epsilon}$$

Idempotent computation

Construction

Let $\underline{w} = (i_1, \dots, i_n)$ be a reduced expression for w and assume that an idempotent e_n for w has been constructed. Let i_{n+1} be such that (w, i_{n+1}) is also reduced, we compute an idempotent e_{n+1} :

Idempotent computation

Construction

Let $\underline{w} = (i_1, \dots, i_n)$ be a reduced expression for w and assume that an idempotent e_n for w has been constructed. Let i_{n+1} be such that (w, i_{n+1}) is also reduced, we compute an idempotent e_{n+1} :

1. Compute the tensor product:

$$B_w \otimes B_{i_{n+1}} \simeq \bigoplus_{x \in N(w)} B_x^{k_x}.$$

We assume here $k_x = 1$.

Idempotent computation

Construction

Let $\underline{w} = (i_1, \dots, i_n)$ be a reduced expression for w and assume that an idempotent e_n for w has been constructed. Let i_{n+1} be such that (w, i_{n+1}) is also reduced, we compute an idempotent e_{n+1} :

2. For each $x \in N(w)$, find projection and inclusion:

$$p_{w, i_{n+1}}^x = \begin{array}{c} \boxed{x} \\ \text{---} \\ \text{---} \\ \text{---} \\ \boxed{w} \end{array}, \quad \iota_{w, i_{n+1}}^x = \begin{array}{c} \boxed{w} \\ \text{---} \\ \text{---} \\ \text{---} \\ \boxed{x} \end{array}.$$

Idempotent computation

Construction

Let $\underline{w} = (i_1, \dots, i_n)$ be a reduced expression for w and assume that an idempotent e_n for w has been constructed. Let i_{n+1} be such that (w, i_{n+1}) is also reduced, we compute an idempotent e_{n+1} :

3. For each x compute the scalars $\kappa_{x,n+1}$ such that:

$$p_{w,i_{n+1}}^x \circ l_{w,i_{n+1}}^x = \begin{array}{c} \boxed{x} \\ \text{---} \\ \boxed{w} \\ \text{---} \\ \boxed{w} \\ \text{---} \\ \boxed{x} \end{array} = \kappa_{x,n+1} \cdot \boxed{x}$$

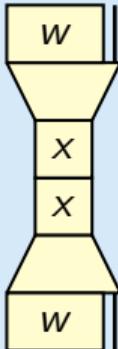

Note that $\kappa_{(w,i_{n+1}),n+1} = 1$.

Idempotent computation

Construction

Let $\underline{w} = (i_1, \dots, i_n)$ be a reduced expression for w and assume that an idempotent e_n for w has been constructed. Let i_{n+1} be such that (w, i_{n+1}) is also reduced, we compute an idempotent e_{n+1} :

4. Define e_{n+1} recursively as:

$$e_{n+1} := e_n - \sum_{x \in N(w) \setminus \{(w, i_{n+1})\}} \kappa_{x, n+1}^{-1} \cdot$$

Idempotents in type F_n

As a short hand, we write i instead of s_i . Consider the element $\underline{x} = (2, 4, 5, 3, 2, 4)$. In the branching graph we visualize the decomposition of $B_{x_m} \otimes B_{i_{m+1}}$:

$$\Gamma(243524) = \emptyset \xrightarrow{\text{orange}} 2 \xrightarrow{\text{purple}} 24 \xrightarrow{\text{cyan}} 245 \xrightarrow{\text{green}} 2453 \xrightarrow{\text{orange}} 24532 \xrightarrow{\text{purple}} 245324$$

The idempotents have the form:

$$\begin{aligned} \boxed{2} &= \begin{array}{c} \vdots \\ \vdots \end{array}, & \boxed{24} &= \boxed{2} \begin{array}{c} \vdots \\ \vdots \end{array}, & \boxed{245} &= \boxed{24} \begin{array}{c} \vdots \\ \vdots \end{array}, & \boxed{2453} &= \boxed{245} \begin{array}{c} \vdots \\ \vdots \end{array}, \\ \boxed{24532} &= \boxed{2453} \begin{array}{c} \vdots \\ \vdots \end{array} + \frac{1}{[2]_4} \cdot \begin{array}{c} \boxed{2453} \\ \vdots \\ \boxed{2453} \end{array}, & \boxed{245324} &= \boxed{24532} \begin{array}{c} \vdots \\ \vdots \end{array}. \end{aligned}$$

Idempotents in type H_3

Let $\underline{d} = 232$ and $\underline{x} = \underline{d}123$. The branching graph is:

Idempotents in type H_3

Let $\underline{d} = 232$ and $\underline{x} = \underline{d123}$. The branching graph is:

The idempotents are:

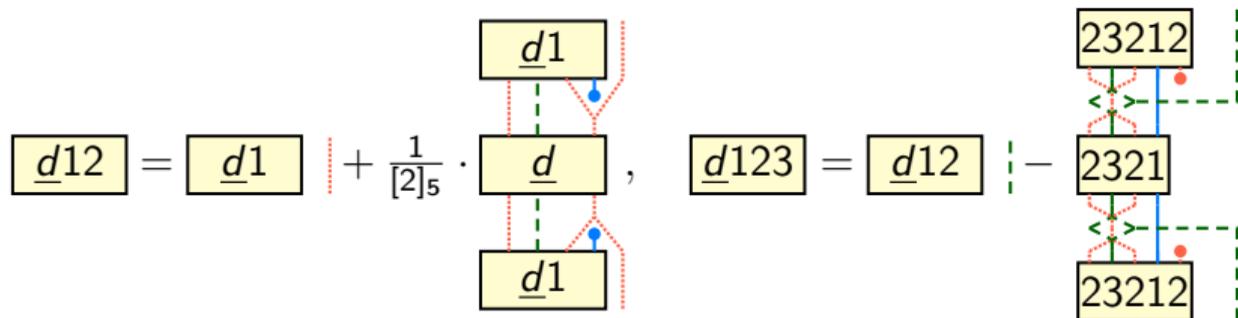

$$\boxed{\underline{d12}} = \boxed{\underline{d1}} \cdot \text{---} + \frac{1}{[2]_5} \cdot \begin{array}{c} \boxed{\underline{d1}} \\ \text{---} \\ \boxed{\underline{d}} \\ \text{---} \\ \boxed{\underline{d1}} \end{array} ,$$

Idempotents in type H_3

Let $\underline{d} = 232$ and $\underline{x} = \underline{d}123$. The branching graph is:

The idempotents are:

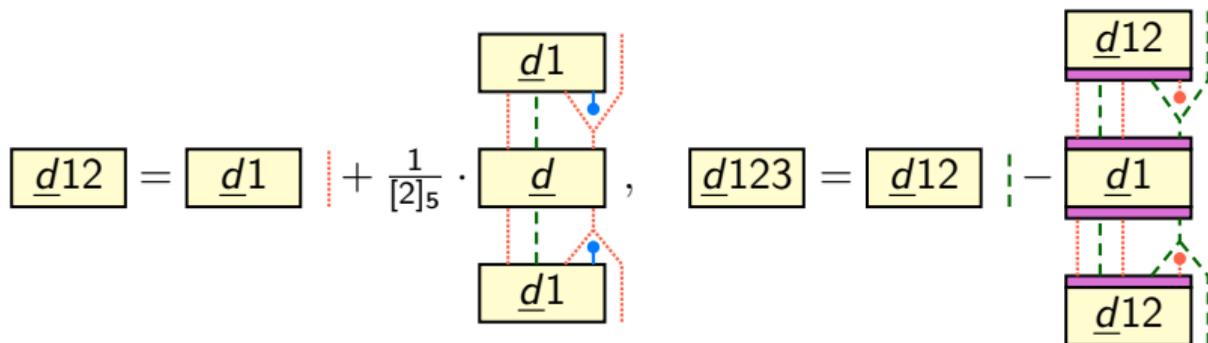

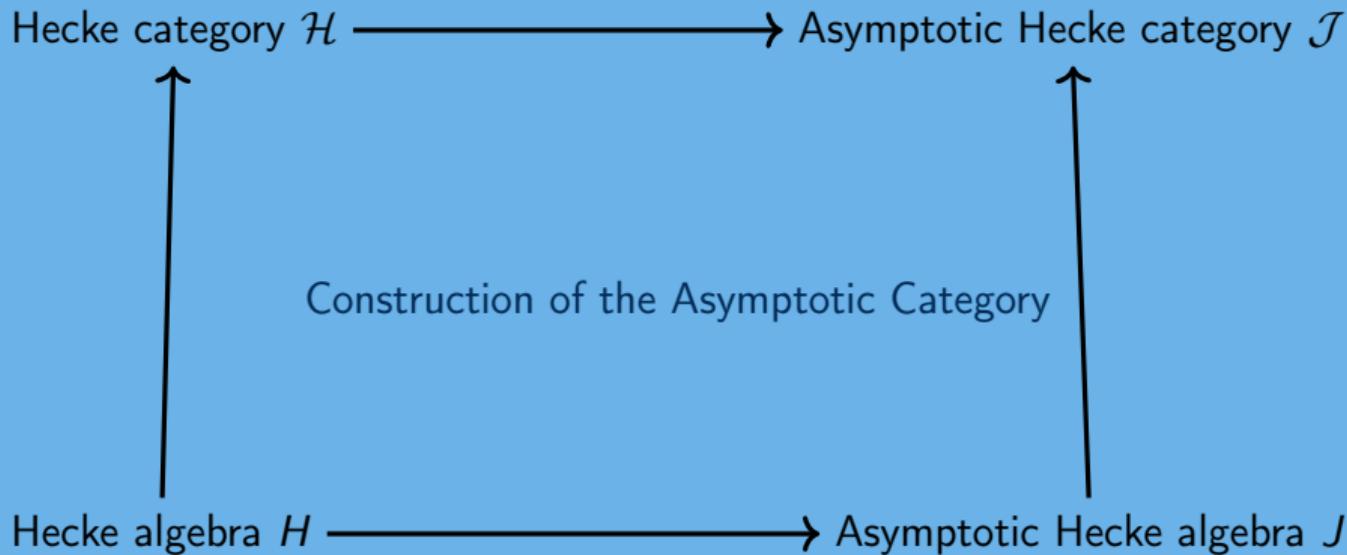

Idempotents in type H_3

Let $\underline{d} = 232$ and $\underline{x} = \underline{d123}$. The branching graph is:

The idempotents are:

Cells and the Asymptotic Algebra

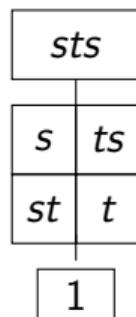

For a Coxeter system (W, S) let $H(W)$ be the Hecke algebra (over $\mathbb{Z}[v^{\pm 1}]$) with Kazhdan–Lusztig basis $\{b_w \mid w \in W\}$. The decomposition of the product of the b_w 's partitions the group W into cells. E.g. type $I_2(3)$:

Big blocks are called *J-cells*, small blocks *H-cells*. The *J-cells* are $\{1\}$, $\{s, t, st, ts\}$, and $\{sts\}$. We have for example:

$$b_s b_s = (v + v^{-1})b_s, \quad b_s b_t = b_{st}, \quad b_{st} b_s = b_{sts} + b_s$$

In the asymptotic algebra:

$$j_s j_s = j_s, \quad j_s j_t = 0, \quad j_{st} j_{ts} = j_s$$

The *asymptotic Hecke algebra* is generated by j_x for $x \in W$, where we kill all summands not from the same cell and lowest degree.

Motivation for the asymptotic Hecke category

To categorify the asymptotic Hecke algebra J , we want to change \mathcal{H} into a new category \mathcal{J} such that

$$B_s \otimes B_s \simeq B_s(+1) \oplus B_s(-1) \quad \text{becomes} \quad J_s \otimes J_s \simeq J_s.$$

Problem: The direct sum is *not* canonical. We can modify p_{+1} and i_{-1} in the direct sum decomposition:

The diagrammatic equation shows the modification of the projector p_{+1} . On the left, p_{+1} is represented by a blue line that starts from a top dashed line, goes down, and then splits into two lines that meet at a bottom dashed line. The angle of the split is labeled $\frac{\alpha_s}{2}$. On the right, p'_{+1} is shown as a sum of two terms. The first term is a blue line that starts from a top dashed line, goes down, and then has a small blue dot on the bottom dashed line. The second term is a blue line that starts from a top dashed line, goes down, and then splits into two lines that meet at a bottom dashed line, identical to the diagram for p_{+1} . The entire right-hand side is multiplied by $\lambda \alpha_s$.

To imitate the construction from the algebra level, we need to relate different graded summands.

Relative Hard Lefschetz for Soergel bimodules

For $B \in \mathbb{S}\text{Bim}$, let $\tau_{\leq i} B$ denote the summands of degree $\leq i$. We can project onto them canonically. The *perverse cohomology* is defined as $H^i(B) = (\tau_{\leq i} B / \tau_{\leq i-1} B)(-i)$.

Theorem (Relative Hard Lefschetz, Elias–Williamson '16)

Let $x, y \in W$ be arbitrary and let ρ be dominant regular ($\partial_s(\rho) = 1$ for all s). The multiplication map

$$\eta : B_x \otimes_R B_y \rightarrow B_x \otimes_R B_y(2), \quad b \otimes b' \mapsto b \otimes \rho b' = b\rho \otimes b'$$

induces isomorphisms (for all $i \geq 0$)

$$\eta^i : H^{-i}(B_x \otimes_R B_y) \xrightarrow{\sim} H^i(B_x \otimes_R B_y).$$

For any j_z summand of $j_x j_y$ in a -value k , we can use the Lefschetz operator with the canonical projection $B_x \otimes B_y \rightarrow B_z(-k)$ and inclusion $B_z(+k) \rightarrow B_x \otimes B_y$ to define a new monoidal category \mathcal{J} .

Construction of \mathcal{J}_c

Let W be a Coxeter group, $c \subseteq W$ a two-sided cell, and a the value of the a -function on c . Assume ρ is dominant regular. We construct the asymptotic category \mathcal{J}_c as follows:

1. $\mathcal{H}_{\geq c}$ is the category with objects $B_z(m)$ for $z \geq c$ and $m \in \mathbb{Z}$ (no monoidal product).
2. $I_{>c}$ is the tensor ideal of all morphisms factoring over objects from bigger cells.
3. \mathcal{H}'_c is the quotient $\mathcal{H}_c/I_{>c}$.
4. \mathcal{J}_c is the subcategory of \mathcal{H}'_c generated by $J_x := B_x$ for $x \in c$ with monoidal product

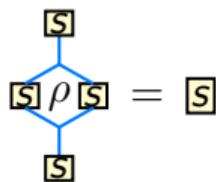

$$B \star B' := H^{-a}(B \otimes B').$$

For h a diagonal H -cell we also write \mathcal{J}_h . This is a fusion category.

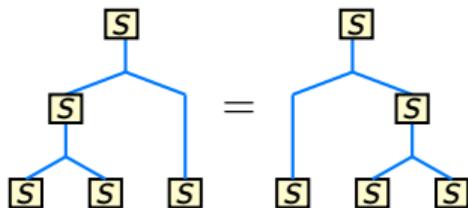

A trivial asymptotic category

Consider type A_1 , so the group $W = \langle s \mid s^2 = 1 \rangle$. Then $c = h = \{s\}$ is a J/H -cell.

We have $J_s \otimes J_s \simeq J_s$:

The associator is trivial:

This is a fusion category with only one object. Hence the asymptotic category is $\mathcal{J}_c \simeq \text{Vec}$.

A non-trivial asymptotic category

Consider type $A_2 = I_2(3)$ with cell $c = \{s, t, ts, st\}$.

A non-trivial asymptotic category

Consider type $A_2 = I_2(3)$ with cell $c = \{s, t, ts, st\}$.

The element sts lies in a higher cell, hence the following map is zero in the quotient:

$$0 = \begin{array}{c} \text{---} \\ | \\ | \\ \boxed{sts} \\ | \\ | \\ \text{---} \end{array} = \begin{array}{c} | \\ | \\ \text{---} \\ | \\ | \end{array} + \begin{array}{c} | \\ \bullet \\ | \\ \text{---} \\ | \\ \bullet \\ | \end{array} \in \mathcal{J}_c.$$

A non-trivial asymptotic category

Consider type $A_2 = I_2(3)$ with cell $c = \{s, t, ts, st\}$.

The element sts lies in a higher cell, hence the following map is zero in the quotient:

$$0 = \begin{array}{c} \text{---} \\ | \\ | \\ \boxed{sts} \\ | \\ | \\ \text{---} \end{array} = \begin{array}{c} | \\ | \\ | \\ | \\ | \end{array} + \begin{array}{c} | \\ | \\ \text{---} \\ | \\ | \end{array} \in \mathcal{J}_c.$$

Specifically, composing with startdot and enddot on opposite sides yields:

$$0 = \begin{array}{c} \bullet \\ | \\ | \\ \boxed{sts} \\ | \\ | \\ \bullet \end{array} = \begin{array}{c} \bullet \\ \diagdown \\ \diagup \\ \bullet \end{array} + \begin{array}{c} \diagdown \\ \bullet \\ \diagup \\ \bullet \end{array} \in \mathcal{J}_c.$$

A non-trivial asymptotic category

Consider type $A_2 = I_2(3)$ with cell $c = \{s, t, ts, st\}$.

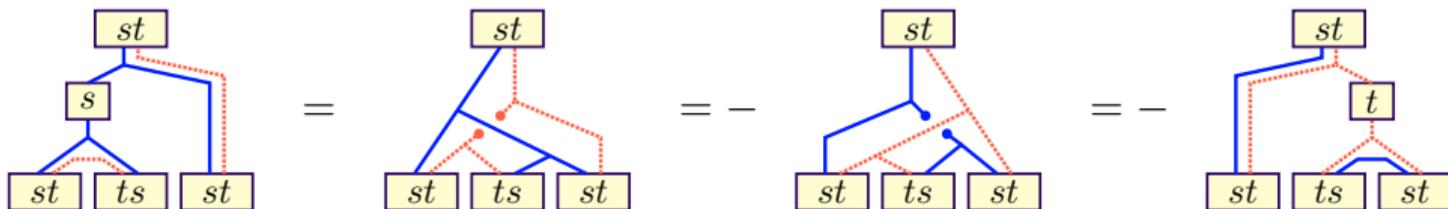

$$\begin{array}{c} \text{red} \\ \diagdown \\ \text{blue} \\ \diagup \\ \text{red} \end{array} = - \begin{array}{c} \text{red} \\ \diagup \\ \text{blue} \\ \diagdown \\ \text{red} \end{array} \in \mathcal{J}_c$$

A non-trivial asymptotic category

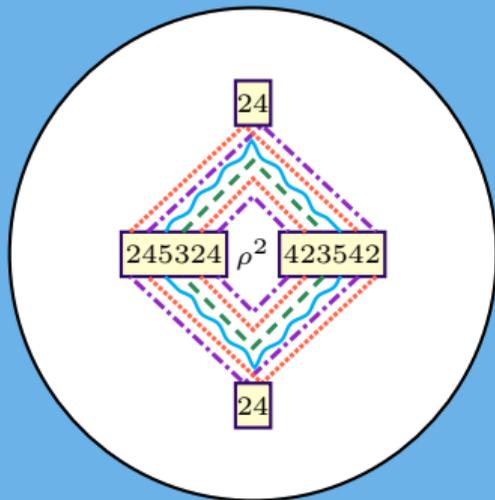

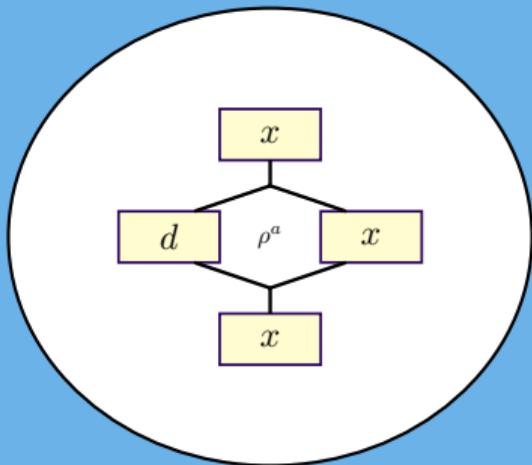

Consider type $A_2 = I_2(3)$ with cell $c = \{s, t, ts, st\}$.

$$\begin{array}{c} \cdot \\ \diagdown \\ \diagup \\ \cdot \end{array} = - \begin{array}{c} \cdot \\ \diagup \\ \diagdown \\ \cdot \end{array} \in \mathcal{J}_c$$

We can use this relation to show that there is a non-trivial $6j$ -symbol:

Dimensions in the asymptotic Category

Dimension of objects

Let \mathcal{C} be a \mathbb{k} -linear fusion category with *pivotal structure*, i.e. a collection of isomorphisms $a_X : X \xrightarrow{\sim} X^{**}$ natural in X with $a_{X \otimes Y} = a_X \otimes a_Y$. For $X \in \mathcal{C}$ a dual is an object X^* if there are maps $\text{coev}_X : \mathbb{k} \rightarrow X \otimes X^*$ and $\text{ev}_X : X^* \otimes X \rightarrow \mathbb{k}$ written

$$\text{coev}_X = \begin{array}{c} X \quad X^* \\ \text{---} \\ \cup \\ \text{---} \end{array}, \quad \text{ev}_X = \begin{array}{c} \text{---} \\ \cap \\ X^* \quad X \\ \text{---} \end{array}, \quad \text{such that: } \begin{array}{c} X \\ \text{---} \\ \cup \\ \text{---} \\ X \end{array} = \begin{array}{c} X \\ \text{---} \\ | \\ \text{---} \\ X \end{array}, \quad \begin{array}{c} \text{---} \\ \cap \\ X^* \quad X^* \\ \text{---} \end{array} = \begin{array}{c} X^* \\ \text{---} \\ | \\ \text{---} \\ X^* \end{array}.$$

For a morphism $f : X \rightarrow X$ we define the trace as $\text{tr}(f) \in \mathbb{k}$ and the dimension as $\dim(X) = \text{trace}(\text{id}_X)$:

$$\text{tr}(f) \text{id}_1 = \begin{array}{c} \text{---} \\ \cup \\ X^{**} \quad X^* \\ \cap \\ X \\ \text{---} \end{array}$$

Dimensions in the asymptotic Category

Let $h = \{x_0 = d, x_1, \dots, x_n\}$ be an H -cell of a -value k . We want to compute the dimensions of the objects in \mathcal{J}_h .

Dimensions in the asymptotic Category

Let $h = \{x_0 = d, x_1, \dots, x_n\}$ be an H -cell of a -value k . We want to compute the dimensions of the objects in \mathcal{J}_h . For $x \in h$ we denote a degree $-k$ map including B_d into $B_x \otimes B_{x^*}$ by incl_x .

Theorem

Fix a dominant regular element ρ and $x \in h$. Fix $\text{incl}_x: B_d \rightarrow B_x \otimes B_{x^*}$ of degree $-k$. Then λ_x and μ_x (defined by the diagrams below) are nonzero if and only if $\text{incl}_x \notin I_c$, in which case the ratio μ_x/λ_x is independent of ρ and equals the categorical dimension of J_x in \mathcal{J}_c .

$$\begin{array}{c}
 \boxed{x} \\
 | \\
 \boxed{d} \quad \rho^k \quad \boxed{x} \\
 | \\
 \boxed{x}
 \end{array} = \lambda_x \cdot \boxed{x}, \quad
 \begin{array}{c}
 \boxed{d} \\
 | \\
 \boxed{x} \quad \rho^k \quad \boxed{x^*} \\
 | \\
 \boxed{d}
 \end{array} = \mu_x \cdot \boxed{d}$$

Example: Type A_1

Consider the cell $h = \{s\}$ of a -value 1 in type A_1 .
We choose $\rho = \frac{\alpha_s}{2}$ and compute:

$$\begin{array}{c} \boxed{S} \\ \diagdown \quad \diagup \\ \boxed{S} \quad \rho \quad \boxed{S} \\ \diagup \quad \diagdown \\ \boxed{S} \end{array} = \boxed{S}$$

Therefore, the dimension of J_s in \mathcal{J}_h is 1.

Example: Type $I_2(5)$

Consider the cell $h = \{s, sts\}$ of a -value 1 in type $I_2(5)$. We have $j_{sts}^2 = j_s + j_{sts}$. We choose $\rho = \frac{\alpha_s}{2} + \frac{\alpha_t}{2}$ and compute:

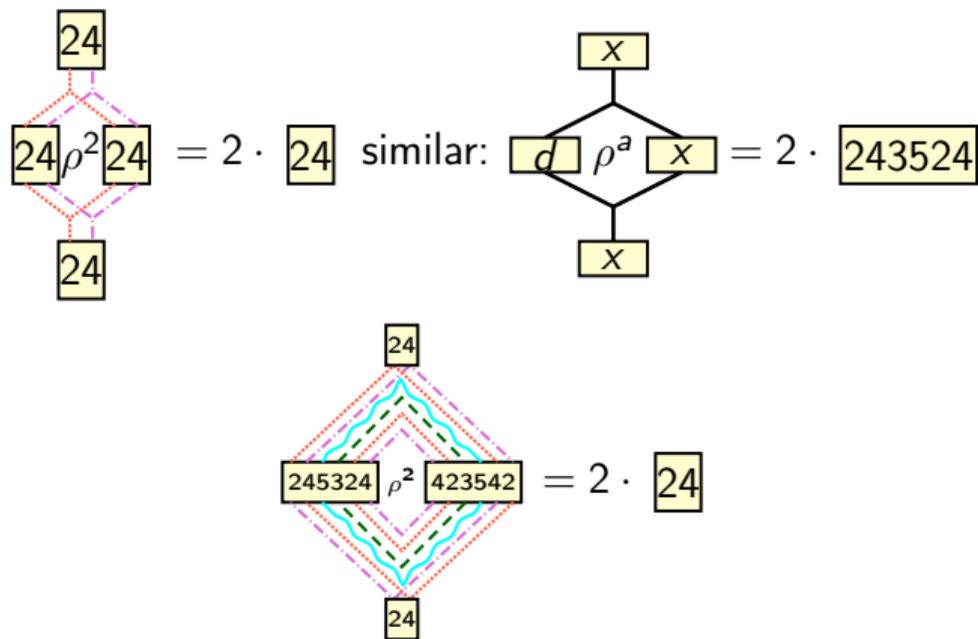

The diagram shows four equations involving diagrams with boxes labeled 'sts' and 's' and regions labeled with the Greek letter rho. The first diagram is a triangle with 'sts' boxes at the top and bottom vertices and 's' boxes at the middle vertices. The second diagram is a diamond with 's' boxes at the top and bottom vertices and 'sts' boxes at the left and right vertices. The third diagram is a hexagon with 's' boxes at the top and bottom vertices and 'sts' boxes at the two side vertices. The fourth diagram is a hexagon with 's' boxes at the top and bottom vertices and 'sts' boxes at the two side vertices, with two red dots on the left side. The equations are:

$$\begin{aligned} \text{Diagram 1} &= \partial_s(\rho) \text{Diagram 2}, \\ \text{Diagram 3} &= \text{Diagram 4} = \text{Diagram 5} + \frac{1}{[2]} \text{Diagram 6} = \partial_s(\rho)[3] \text{Diagram 7} \end{aligned}$$

Therefore, the dimension of J_{sts} in \mathcal{J}_h is $[3] = \frac{1+\sqrt{5}}{2}$.

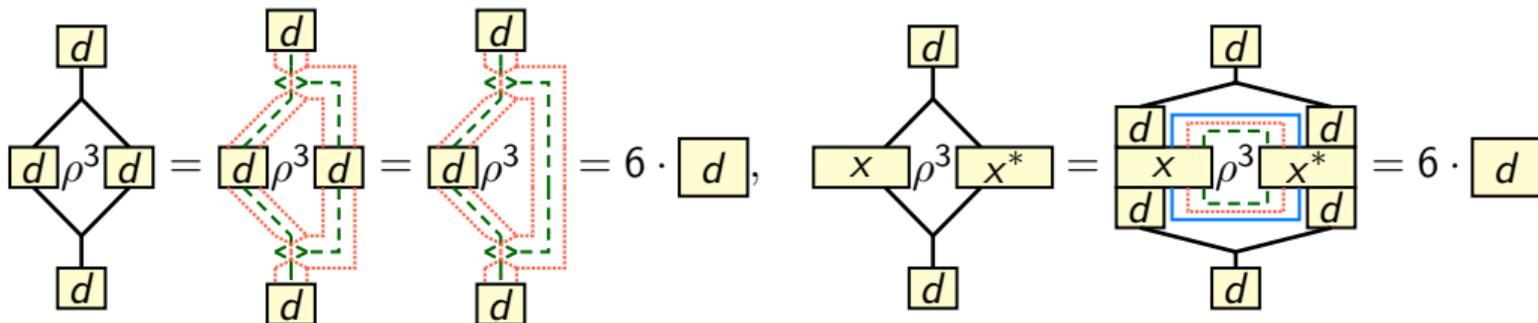

Example: Type F_n

Consider the cell $h = \{d = 24, x = 243524\}$ of a -value 2 in type F_n for $n \geq 5$. The dimension of A_x is again 1:

Example: Type H_3

Consider the cell $h = \{d = 232, x = 232123\}$ of a -value 3 in type H_3 . We can choose $\rho = \frac{9\varphi+6}{2}\alpha_1 + (5\varphi+4)\alpha_2 + \frac{5\varphi+5}{2}\alpha_3$ and the dimension of J_x is also 1:

One step in the example of type H_3
